EXECUTIVE SUMMARY

City of Abernathy (“City”) is presented an evaluation of the City’s water supply life expectancy at current demands and an analysis of the effect on well life expectancy with an additional 131,400,000 gallons per year of use by Golden Spread Electric Cooperation (“Golden Spread”). This evaluation includes a preliminary examination of the volume of water supply available and determination of ability to produce and supply the water needs for the citizens of Abernathy within regulatory requirements. The current system consists of five (5) wells and approximately 12 total miles of collection and transmission pipelines

The scope of this report is limited to the above description of the water system and the information provided by the City of Abernathy. It makes use of readily available data furnished by the City and includes historic data.

DESCRIPTION OF EXISTING FACILITIES

The City receives water from Wells No. 1, 4, 5, 6 and 7 located on property owned by the City. These wells sit along the water supply transmission line and supply 100% of the water needs of the citizens of Abernathy. All City-owned wells are completed in the Ogallala Aquifer, which is the region’s major water supply source. A map showing the City’s existing infrastructure can be seen in Figure 1.

CITY OF ABERNATHY
WELL COLLECTION SYSTEM
EXISTING SYSTEM

Project No: 0028.11 Date: 8-7-14

Figure 1. City of Abernathy Water Supply System

A project is currently underway to expand the water transmission system to allow for more efficient operation of the existing wells. The project includes replacing the 10- and 12-inch line between Well #4 and Well #1 with a 14-inch higher pressure transmission line. This 14-inch line will match the existing transmission line which is currently installed from Well #1 to the City. The increase in line diameter and pressure class will allow the wells to operate under less head pressure, increasing the ultimate capacity of the City's water supply system.

INTEGRATED WATER RESOURCE EVALUATION

Two analyses of the City's current water sources were performed. The first analysis projects well life at the City's average current usage of 169,400,000 gal/year. The second analysis took into consideration an increase of 131,400,000 gal/year of additional water use by Golden Spread.

WELL FIELD LIFE AT CURRENT USAGE

The Ogallala Aquifer in the South Plains Region of Texas has experienced high volume regional pumping for agriculture and municipal supply which has contributed to the aquifers regionally declining levels. The City's wells are no exception to the declining levels of the aquifer. Data provided by the City, summarized in Table 1, shows how water levels in the wells have historically responded.

| Table 1 Summary of City Well Water Levels | | | | | | |
|--|-----------------------------|---|---|-----------------------------------|--|---|
| Well | Total Depth (ft) | Initial Water Level (ft) | Current Water Level (ft) | Total Decline (ft) | Avg. Yearly Decline (ft/yr) | Avg. Yearly Decline Since 2008 (ft/yr) |
| 1 | 285 | -167.0 | -239.7 | -72.7 | -1.5 | -0.7 |
| 4 | 397 | -198.0 | -252.3 | -54.3 | -1.4 | -0.9 |
| 5 | 351 | -186.0 | -280.8 | -94.8 | -2.8 | -5.3 |
| 6 | 358 | -186.0 | -279.5 | -93.5 | -2.8 | -9.9 |
| 7 | 330 | -247.1 | -274.4 | -27.3 | -5.5 | -5.5 |

The saturated thickness of all the wells has steadily declined over the period of record. Average yearly decline is as little as -1.4 feet per year (ft/yr) and as much as -5.5 ft/yr. Historical information for each well can be seen in Appendix A. The declining water levels match the regional trend. High Plains Water District (HPWD) has a system of observation wells to monitor the aquifer levels in the region. HPWD monitors 122 wells in Hale County and 144 wells in Lubbock County. Table 2 shows the water level trend for those two counties.

| Table 2 Lubbock and Hale County Water Level History | | | |
|--|-------------------------------------|-------------------------------------|-------------------------------------|
| County | Average Change 2004 to 2014 (ft) | Average Change 2009 to 2014 (ft) | Average Change 2013 to 2014 (ft) |
| Hale | -15.84 | -10.02 | -1.65 |
| Lubbock | -4.54 | -4.71 | -0.96 |

The average yearly decline in Hale County from 2004 to present is -1.58 ft/yr, while the average of 2009 to present is a steeper decline of -2 ft/yr. Sharper water level declines of the past five years match the trend seen in Wells 5, 6 and 7. This is most likely attributed to the recent drought and higher water usage that corresponds to drought conditions. The aerial imagery in Figure 2 shows there are high concentrations of center pivot irrigation close to Wells 5, 6 and 7.

Figure 2. Irrigation Near the Well Field

The concentration of irrigation is dense in the area of Wells 5, 6 and 7 making these wells susceptible to drought. To the north and east of Wells 5, 6 and 7 the saturated thickness of the aquifer becomes too thin for large scale pumping that is needed for irrigation and municipal supply. Irrigation occurs around Wells 1 and 4, but center pivots are less dense.

Due to the relatively small areas of water rights owned by the City and the high concentration of irrigation in the area it is best to look at well life on a regional basis. HPWD has an observation well (23-03-802) adjacent to Wells 5, 6 and 7. From 1971 to 1988 water levels declined an average of -2.3 ft/yr. From 2004 to 2014 water levels declined an average of -3.56 ft/yr. From 1971 to 2014 water levels declined an average of -3.08 ft/yr. Detailed water level data and a map of the observation well can be found in Appendix B. The water level declines of this observation well are consistent with the declines recorded in the City well field. Declines in aquifer's saturated thickness are a regional issue and are not limited to the City's well field.

To project the remaining life of the City well field the current saturated thickness was found by subtracting the static water level from the total well depth. An operational saturated thickness was

determined by looking at average drawdowns of each individual well and minimum pump submergence for proper operation. The operational saturated thickness is the thickness remaining that the well can operate without the pump losing suction due to drawdown. Table 3 shows the expected life remaining when taking this into account.

| Table 3 Expected Remaining Individual Well Life | | | | | | | |
|--|------------------|----------------------------------|----------------------------------|--|--------------------|-----------------------------|--------------------------|
| Well | Total Depth (ft) | Initial Saturated Thickness (ft) | Current Saturated Thickness (ft) | Current Operational Saturated Thickness (ft) | Total Decline (ft) | Avg. Yearly Decline (ft/yr) | Well Life Remaining (yr) |
| 1 | 285 | 118.0 | 45.3 | 18.3 | -72.7 | -1.5 | 12.1 |
| 4 | 397 | 199.0 | 144.7 | 124.7 | -54.3 | -1.4 | 89.5 |
| 5 | 351 | 165.0 | 70.2 | 41.2 | -94.8 | -2.8 | 14.8 |
| 6 | 358 | 172.0 | 78.5 | 51.5 | -93.5 | -2.8 | 18.7 |
| 7 | 330 | 82.9 | 55.6 | 34.6 | -27.3 | -5.5 | 6.3 |

The data for Well 7 is from 2009 to present. All other wells have historical data from the 1970's to present. Well 4 has an expected life that is inconsistent with the other four wells, which is likely attributed to less irrigation in the immediate area and the well having a higher saturated thickness than the other four wells. It is likely that with decreasing saturated thickness in the other wells, Well 4 will be operated more and the actual life will be less than the 89.5 years projected in Table 3.

The data in Table 3 for Wells 1, 4, 5 and 6 takes into account water levels from the 1970's to the present. It is possible that water use today is different than the average over a long period. Drought in the region will have a direct effect on water use. Table 4 shows data collected in the previous 6 years.

| Table 4 Water Levels 2008 – 2014 | | | | | |
|---|------------------|----------------------------------|--|--|--------------------------------------|
| Well | Total Depth (ft) | Current Saturated Thickness (ft) | Current Operational Saturated Thickness (ft) | Avg. Yearly Decline Since 2008 (ft/yr) | Projecting 2008 - Present Trend (yr) |
| 1 | 285 | 45.3 | 18.3 | -0.7 | 25.0 |
| 4 | 397 | 144.7 | 124.7 | -0.9 | 141.1 |
| 5 | 351 | 70.2 | 41.2 | -5.3 | 7.8 |
| 6 | 358 | 78.5 | 51.5 | -9.9 | 5.2 |
| 7 | 330 | 55.6 | 34.6 | -5.5 | 6.3 |

Wells 5, 6 and 7 have experienced higher than average decreases in water levels since 2008. Drought conditions have been prevalent through most of the recent years forcing an increase in irrigation water to make up for lack of rainfall. If drought conditions persist, water levels will continue the steep decline.

Wells 1 and 4 have experienced less decline since 2008 compared to historical declines. The declines in Wells 1 and 4 are less than the regional average for Hale County. The lower than average declines are most likely due to less irrigation in the area and higher aquifer saturated thickness surrounding Well 4.

Remaining life of the City's well field is a function of all wells operated together for optimal production, quality, cost and life. Table 5 takes the average of each of the current operational saturated thickness and divides by the average declines over the period of record to develop an estimated remaining well field life.

| Table 5 Expected Remaining Well Field Life | | | | | |
|---|------------------|--|--------------------|-----------------------------|--------------------------|
| Well | Total Depth (ft) | Current Operational Saturated Thickness (ft) | Total Decline (ft) | Avg. Yearly Decline (ft/yr) | Well Life Remaining (Yr) |
| 1 | 285 | 18.3 | -72.7 | -1.5 | 6.6 |
| 4 | 397 | 124.7 | -54.3 | -1.4 | 44.8 |
| 5 | 351 | 41.2 | -94.8 | -2.8 | 14.8 |
| 6 | 358 | 51.5 | -93.5 | -2.8 | 18.5 |
| 7 | 330 | 34.6 | -27.3 | -5.5 | 12.4 |
| Well Field Average | | 54.1 | -68.5 | -2.8 | 19.4 |

Based on the average decline across the well field and current saturated thickness of each well, the City can expect its well field to last about 19 years based on historical conditions and usage.

WELL FIELD LIFE WITH ADDITIONAL GOLDEN SPREAD USAGE

Golden Spread Electric Cooperative has proposed to increase the City's water use by as much as 131,400,000 gallons per year or 77.5% of current average use. The goal of this analysis is to determine how the proposed increased usage would affect the life of the well field.

The proposed usage of Golden Spread is shown in Table 6 compared to the City's current usage and operation.

**Table 6
Proposed Golden Spread Usage and City Historical Data**

| | | |
|--|---------------|------------------|
| Estimated Increase in Water Needs | Minimum | Peak |
| Gallon/Minute | 450 | 500 |
| Gallon/Hour | 27,000 | 30,000 |
| Gallon/Day (12 Hour per day operation) | 324,000 | 360,000 |
| Gallon/Year | 118,260,000 | 131,400,000 |
| | | |
| City Current Water Use | Year (Gallon) | Day (Gallon) |
| 2009 | 163,600,000 | 448,219 |
| 2010 | 152,100,000 | 416,712 |
| 2011 | 201,100,000 | 550,959 |
| 2012 | 163,600,000 | 448,219 |
| 2013 | 167,800,000 | 459,726 |
| Average | 169,640,000 | 464,767 |
| | | |
| Anticipated Increase in Volume (Gallon/Year) | | Percent Increase |
| Minimum | 287,900,000 | 69.7% |
| Peak | 301,040,000 | 77.5% |

The projected increased Golden Spread usage is a significant increase when compared to the current City water use. Irrigation is the biggest water user in the region. Over 90% of Ogallala withdrawals in the Texas High Plains are for irrigation; however, the Ogallala is essentially a closed basin and withdrawals have greatly exceeded recharge, resulting in a severe decline of groundwater levels since irrigation development began. In some areas, more than 50% of the predevelopment saturated thickness has been pumped, and groundwater levels have dropped over 50 m (McGuire, 2003).

HPWD rules allow for a production rate of 1.5 ac-ft per contiguous acre per year. This rule allows irrigation for one section of land to be up to 18" of application per year. If area farmers use the full allotted amount the usage would be 960 ac-ft per section. Converting 960 ac-ft/yr to an average gallon per minute (gpm) would equate to each section farmed producing a yearly average of 595 gallons per minute per section over the course of a year. With the additional use proposed by Golden Spread the City expects to deliver up to a total volume of 301,040,000 gallons per year, or 924 ac-ft/year. With irrigation of the region being the largest water user, it becomes apparent that irrigation will control the water levels in the aquifer and therefore the remaining life of the City wells.

The current annual usage for the City is 169,640,000 gallons which is the equivalent to 520 ac-ft/year or 0.54 sections (345.6 acres) of irrigation. With the expected increased volume from Golden Spread the City could deliver up to 301,040,000 gallons, equivalent to 924 ac-ft/yr or 0.96 sections (614.4 acres) of irrigation.

TRANSMISSION SYSTEM ANALYSIS

The current transmission system is able to deliver up to 1,252,800 gal/day, or 870 gpm to the City distribution system. The peak daily demand occurred in July 2011 and was 1,107,000 gal, or 769 gpm. The pipeline project that is currently underway will increase the system capacity up to an expected 1,480 gpm ultimate capacity with an installed well capacity of 1,295 gpm. In the scenario that the City repeats its peak day and Golden Spread takes its estimated peak volume of 360,000 gallons per day, the City would need the capacity to deliver 1,467,000 gal or 1,019 gpm. The capacity to meet peak day demands and peak Golden Spread volumes are only possible after the completion of the current pipeline project. Table 7 summarizes the transmission system capacity volumes required.

| Table 7 Operational Scenario for Well Field | | |
|--|-----------|-------|
| Scenario | Gal / Day | GPM |
| City Peak Day | 1,107,000 | 769 |
| City and Golden Spread Peak Day | 1,467,000 | 1,019 |
| Transmission System - Current | 1,252,800 | 870 |
| Transmission System - Future | 1,864,800 | 1,295 |
| Transmission System - Ultimate | 2,131,200 | 1,480 |

Transmission System - Current represents the volume of water currently deliverable to the City including wells and transmission pipeline. Transmission System - Future represents the volume of water that can be delivered after the pipeline project is complete with currently installed wells operating at full capacity. Transmission System - Ultimate represents the volume of water that is expected to be available if additional wells are added to the system after the pipeline project is complete. This analysis does not consider the City's ability to meet peak conditions during periods of well downtime or maintenance.

CONCLUSION

The water supply future of the City depends on irrigation in the region. Even with the additional use of Golden Spread the City's total yearly water use would equal roughly one section of yearly irrigation. Declining aquifer levels show the majority of the wells have experienced large declines in water levels. If the trend from the 1970's to present continues the City should expect their water resources to last about 19 years. If the region stays in drought conditions the majority of the City's wells could be below pumping levels in 10 years. These projections do not take into account any change in rules or allowable pumping limits. Wells 5, 6 and 7 are the most susceptible to the declining water levels and appear to be the first wells that will go dry. Declining levels in the City's water rights areas will, at some point, contribute to declining yields in each well.

APPENDIX A
HISTORICAL WELL LEVELS

| Well #1 | | | | | | |
|------------|--------------|---------------|-----------|-----|---------------------|-----------------------------|
